

Motivation

- Meta learning (learning to learn) algorithms facilitate few-shot learning
- Model-agnostic meta learning (MAML) [1]
 - Meta-learning phase: learn from tasks $T_1 \dots T_n$
 - Target learning phase: few shot learning on T_{n+1}
- The good:**
 - Model-agnostic: no requirement for the network structure
 - Very little labeled data needed at the target phase
- The bad:**
 - A lot of labeled data needed at the meta-learning phase
 - Tasks $T_1 \dots T_n$ need to be drawn from the same distribution as the target - we need good knowledge of the target domain

Our idea

Keep the general flow of MAML but use unlabeled data for meta-learning!

Algorithm 1: Unsupervised Meta-learning with Tasks constructed by Random sampling and Augmentation (UMTRA)

require: N : class-count, N_{MB} : meta-batch size, N_U : no. of updates
require: $\mathcal{U} = \{x_1 \dots x_N\}$ unlabeled dataset
require: α, β : step size hyperparameters
require: \mathcal{A} : augmentation function
 randomly initialize θ ;
while not done do
 for i **in** $1 \dots N_{MB}$ **do**
 Sample N data points $x_1 \dots x_N$ from \mathcal{U} ;
 $\mathcal{T}_i \leftarrow \{x_1, \dots, x_N\}$;
 end
 foreach \mathcal{T}_i **do**
 Generate training set $\mathcal{D}_i = \{(x_1, 1), \dots, (x_N, N)\}$;
 $\theta'_i = \theta$;
 for j **in** $1 \dots N_U$ **do**
 Evaluate $\nabla_{\theta'_i} \mathcal{L}_{\mathcal{T}_i}(f_{\theta'_i})$;
 Compute adapted parameters with gradient descent: $\theta'_i = \theta'_i - \alpha \nabla_{\theta'_i} \mathcal{L}_{\mathcal{T}_i}(f_{\theta'_i})$;
 end
 Generate validation set for the meta-update $\mathcal{D}'_i = \{(\mathcal{A}(x_1), 1), \dots, (\mathcal{A}(x_N), N)\}$
 end
 Update $\theta \leftarrow \theta - \beta \nabla_{\theta} \sum \mathcal{L}_{\mathcal{T}_i}(f_{\theta'_i})$ using each \mathcal{D}'_i ;
end

Unsupervised Meta-learning with Tasks constructed by Random sampling and Augmentation (UMTRA)

- Start with an unlabeled data set D of samples
 - We assume a large number of classes C present, but we don't know the class of each sample
- Generate synthetic one shot training tasks $T_1 \dots T_n$
 - Random selection of samples with artificial labels
 - The large number of classes ensures high likelihood that classes are different
- Create validation data by augmentation $x_v = \mathcal{A}(x)$
 - Augmentation type varies by domain, the objective is to maintain class membership of the augmented data
 - Augmentation on image type data (Omniglot | MiniImageNet)

- On video: use frame selection to create augmented video
 - C3D architecture
 - Sample a sequence of length 16 from each video
 - Kinetics for meta-learning and UCF101 for test

Experiments

- Few shot learning benchmarks: outperforms other unsupervised algorithms and alternates for best with CACTUs-MAML [2].
- Massive reduction of required labeled data: 25000 to 25 for Omniglot (5,5) for 95.43% vs 98.83 vs MAML.

Works on video classification as well:

Test on **all samples** of each class by looking at just **one example** for train

Algorithm	Test Accuracy / F1-Score
Training from scratch	29.30 / 20.48
Pre-trained on Kinetics	45.51 / 42.49
UMTRA on unlabeled Kinetics (ours)	60.33 / 58.47
Supervised MAML on Kinetics	71.08 / 69.44

Works on unbalanced datasets (CelebA used for face recognition)

Algorithm (N, K)	(5, 1)	(5, 5)	(5, 10)
Training from scratch	26.86	39.65	50.61
UMTRA	33.43	50.19	58.84
